In this paper, we derive some estimators of the scale parameter of half-logistic				
distribution based on multiply Type-II hybrid censoring. First, we derive the				
maximum likelihood estimator (MLE) for the scale parameter. Since the likelihood				
equation has not explicit solution, we obtain the approximate maximum likelihood				
estimators (AMLEs) using Taylor series expansions. We also obtain the Bayesian				

maximum likelihood estimator (MLE) for the scale parameter. Since the likelihood equation has not explicit solution, we obtain the approximate maximum likelihood estimators (AMLEs) using Taylor series expansions. We also obtain the Bayesian estimator by proposed prior distribution. Second, we obtain the asymptotic confidence interval (CI) using the proposed estimators. Finally, we compare the proposed estimators in the sense of bias and the mean squared error (MSE) through Monte Carlo simulation. The Bayesian estimator is generally more efficient than MLE and AMLE in the sense of MSE, but the CI based on the Bayesian estimator is wider than the corresponding CI based on the MLE and AMLEs.
